UNIVERSITY OF SWAZILAND

SUPPLEMENTARY EXAMINATION PAPER 2015

TITLE OF PAPER : TOPICS IN STATISTICS (STATISTICAL MODELLING)

COURSE CODE : ST 405

TIME ALLOWED : 3 HOURS

REQUIREMENTS : CALCULATOR AND STATISTICAL TABLES

INSTRUCTIONS : ANSWER ANY FIVE QUESTIONS

Question 1

Derive the deviance as a function of the estimated mean for the Normal, Poisson, Binomial, and Gamma distributions.

(20 Marks)

Question 2

The following data were collected after a food poisoning outbreak. It is suspected that the potato salad, the crab salad or both were the cause. The contingency table below shows the results of a random survey of 304 diners: whether they were sick (food-poisoned) and the food that they ate.

	Potato Salad		No Potato Salad	
	Crab Salad	No Crab Salad	Crab Salad	No Crab Salad
Not Sick	80	24	31	23
Sick	120	22	4	0

(a) What is a generalized linear model? What is the saturated model in the context of generalized linear models?

(4 Marks)

(b) A log-linear generalized linear model with a Poisson distribution was fitted to the data. The computer output below shows the analysis of deviance table for these data. Each row of the table refers to a model containing the terms given in the left-hand column of that row and all the rows above it.

```
                         Deviance       Change in Deviance
intercept                 295.253
sick                      294.779          0.474
potato                    169.664        125.115
crab                       73.871         95.793
potato:crab                63.196         10.676
sick:potato                 6.482         56.714
sick:crab                   2.743          3.739
sick:potato:crab        4.123e-10          2.743
```

Find a suitable model for these data and give an interpretation. What can be concluded about the likely cause of the outbreak?

(6 Marks)

(c) How is a Pearson residual defined in this model?

(2 Marks)

(d) Calculate the Pearson residuals for your fitted model. Do they indicate an adequate fit to the data?

(4 Marks)

(e) A colleague suggests that a logistic regression model with sickness as response would be more appropriate for these data than the log-linear model. Describe briefly the different aims of these two approaches, and discuss whether your colleague's suggestion is a good one.

(4 Marks)

Question 3

If we write the probability density function (p.d.f.) for the GLM in the form

$$f(y_i|\theta_i, \emptyset) = exp\left[\frac{y_i\theta_i - m(\theta_i)}{h(\emptyset)}\right] + n(y_i, \emptyset)$$

then prove that E(Y_i) = $m'(\theta_i)$ and Var(Y_i) = $m''(\theta_i)\ h(\emptyset)$.

(20 Marks)

Question 4

If the random variable Y_i follows a Gamma distribution, with scale parameter θ and shape parameter ∅, then it has a p.d.f.

$$f(y_i|\theta_i, \emptyset) = \frac{y_i^{\emptyset-1}\theta_i^{\emptyset}\ e^{-y_i\theta_i}}{\Gamma(\emptyset)}$$

Show that the distribution is a member of the exponential family, and find E(Y_i) and Var(Y_i).

(20 Marks)

Question 5

A doctor is investigating the effect of a woman's age on the success of an IVF (in vitro fertilisation) procedure. She has randomly selected 10 women aged under 35 and 10 women aged at least 35. From hospital records she has obtained the following data, which record the numbers of eggs obtained from the women and the numbers that were fertilised during one IVF procedure. She wants to investigate the effect of the woman's age on the probability of an egg being successfully fertilised. She calls this probability the "fertilisation rate".

Women aged under 35		**Women aged at least 35**	
Number of eggs	***Number of fertilised***	***Number of eggs***	***Number of fertilised***
10	9	7	6
9	7	10	7
7	5	9	5
5	3	8	4
10	9	6	4
7	7	5	1
9	5	7	4
8	8	6	4
7	2	5	2
7	5	7	5

(a) Carry out a suitable exploratory analysis to see whether the fertilisation rate might depend on the woman's age.

(4 Marks)

(b) Let n_i denote the number of eggs and xi the number of fertilised eggs for the *i*th woman. Let π_i denote the fertilisation rate for the *i*th woman.

i) Explain why a binomial distribution may be valid to model the data.

(2 Marks)

ii) Write down the expression for the log likelihood of the observed data, assuming a binomial distribution with different fertilisation rates for each woman. Identify the logit function in your expression.

(2 Marks)

(c) The data are analysed using a generalised linear model, with the logit link. The model assumes constant fertilisation rate within each age group, so contains a constant and age as a covariate. Age is coded as 1 for older women, and 0 for younger women. Part of the output from a computer program is given below.

```
Deviance  =  28.26      (1/df) Scaled Deviance  =  1.57

Variance function:  V(u)  = u*(1-u/eggs)       [Binomial]
Link function    :  g(u)  = log(u/(eggs-u))     [Logit]
```

---

i) Explain why the highlighted value 1.57 is useful, and how it is derived from the other numerical value in the output.

(2 Marks)

ii) Explain what the highlighted expressions V(u) and g(u) are and how their formulae are obtained.

(2 Marks)

iii) The estimated value of the coefficient for age in the generalised linear model is –0.744 and the estimate of the constant is 1.150. Obtain estimates of the predicted success rates for the two types of women.

(4 Marks)

iv) For the model which contains only the constant (i.e. does not take age into account), the value for the scaled deviance is 32.65. State, with reasoning, whether the effect of woman's age is statistically significant.

(2 Marks)

v) Someone else has modelled these data but coded younger women as age = 1 and older women as age = 0. Explain how the results and estimates would be different from those given above.

(2 Marks)

Question 6

Many of the wells used for drinking water in South Asian countries are contaminated with natural arsenic, affecting an estimated 100 million people. Arsenic is a cumulative poison, and exposure increases the risk of cancer and other diseases. A research team. measured all wells in an area and labelled them with their arsenic level as well as a characterization as "safe" or "unsafe", depending on whether the arsenic level was above or below the national standard of 50 micrograms per litre (50 μg/L).

People with unsafe wells were encouraged to switch to nearby private or community wells, or to new wells of their own construction. The amount of water needed for drinking is low enough that adding users to a well would not exhaust its capacity.
A few years later the researchers returned to see who had switched wells and found that 57.5% of the 3020 households with unsafe wells had switched. The team performed a series of GLM analyses to understand the factors predictive of well switching among users of unsafe wells.

A preliminary analysis focused on switching and distance to the nearest safe well, then an obvious variable of interest was the arsenic level of the existing well. To explore the extent to which distance to a safe well might be less of a deterrent when the existing well has high arsenic levels, the research team added an interaction term. The final model adds a social predictor, years of education of the well user. Using the results in APPENDIX A:

(a) For the first model interpret the estimated coefficient of distance, and Estimate the probability of switching for households that have to travel 100 meters to find a safe well and for households that have a safe well right at hand (say, at zero meters), and describe the effect of distance in the probability scale.
(7 Marks)

(b) Interpret the coefficient of log-arsenic in terms of the relative effect of arsenic level on of switching wells. Compare families who have to travel 100 meters to find a safe well when the level of arsenic is 50 and 100.
(6Marks)

(c) Explain briefly the effect of education on well-switching, including how it varies for different types of respondents. For simplicity describe your results in terms of odds, although translation to probabilities would be useful for a general audience.
(7 Marks)

Question 7

A cross-sectional subsample from a Socio-Economic Panel, which collected data on doctor visits before and after a major health care reform that took place in 1997. The reform increased the copayments for prescription drugs by up to 200% and imposed upper limits on the reimbursement of physicians by the state insurance. The full panel dataset was analyzed, and the outcome is the number of doctor visits in a three month period. The predictors of interest are reform, a dummy variable that takes the value 1 after the reform and 0 before, age in years, education in years, a dummy variable for bad health, and the log of income. Three models were fitted to the data as follows;

- A Poisson regression model to estimate the effect of reform. Linear terms age, education and logincome, and the dummy for bad health were used as controls.
- A negative binomial model with the same predictors.
- A zero-inflated Poisson model using the same predictors.

Considering the results obtained (See APPENDIX B) and bearing in mind parsimony and goodness of fit, which of the models used here provides the best description of the data? Make sure you provide a clear justification of your choice.

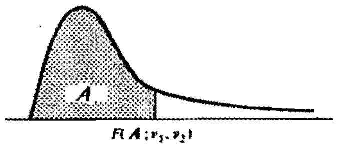
F Distribution

Table C-5 Percentiles of the *F* Distribution

Entry is $F(A;\, \nu_1,\, \nu_2)$ where $P\{F(\nu_1,\, \nu_2) \leq F(A;\, \nu_1,\, \nu_2)\} = A$



$$F(A;\, \nu_1,\, \nu_2) = \frac{1}{F(1 - A;\, \nu_2,\, \nu_1)}$$
